

4.1 Introduction

The central problem of numerical analysis is: given a set of tabular values $(x_0, y_0), (x_1, y_1), (x_2, y_2), \dots, (x_n, y_n)$ satisfying the relation $y = f(x)$, where the explicit nature of $f(x)$ is not known, is to find a simpler function $\phi(x)$ such that $\phi(x)$ and $f(x)$ agree at the set of the tabulated points. Such process is called **interpolation**. If $\phi(x)$ is a polynomial, then the process is called *polynomial interpolation*, and $\phi(x)$ an interpolating polynomial. In this chapter we are concerned with only polynomial interpolation.

Theorem 1 (Weierstrass Theorem). If $f(x)$ is continuous in $x_0 \leq x \leq x_n$, then given $\epsilon > 0$, there exists a polynomial $P(x)$ such that $|f(x) - P(x)| < \epsilon$, for all $x \in (x_0, x_n)$.

So, this gives the justification for approximating a function with a polynomial function.

4.2 Finite Differences

Assume that we have a table of values (x_i, y_i) , $i = 0, 1, \dots, n$ of any function $y = f(x)$. Suppose the values of x are equally spaced, i.e., $x_i = x_0 + ih$, $i = 0, 1, \dots, n$ for some constant h .

Then, the values $y_1 - y_0, y_2 - y_1, \dots, y_n - y_{n-1}$, are called the differences of y . If $y_{i+1} - y_i$ is taken as the i^{th} difference, then we are considering it as a forward difference, if it is taken as the $(i+1)^{th}$ difference then, we are considering it as a backward difference, and if it is taken as $((i+1)/2)^{th}$ then, we are considering it as a central difference. More on these topics in coming subsections.

4.2.1 Forward Differences

The forward difference Δy_i is defined as $\Delta y_i = y_{i+1} - y_i$, where Δ is called the *forward difference operator*. We have,

$$\Delta y_0 = y_1 - y_0, \quad \Delta y_1 = y_2 - y_1, \quad \dots, \quad \Delta y_{n-1} = y_n - y_{n-1} \quad (4.1)$$

These differences Δy_i , $i = 0, 1, \dots, (n-1)$ are called *first forward differences*.

- For $(n + 1)$ points, there are n forward differences.
- These n -forward differences begin at Δy_0 , and end at Δy_{n-1} . There is no Δy_n .

Second Forward Differences

The forward differences of the first forward differences are called second forward differences. They are denoted by $\Delta^2 y_i$, $i = 0, 1, \dots, (n - 2)$. That is,

$$\Delta^2 y_0 = \Delta y_1 - \Delta y_0, \quad \Delta^2 y_1 = \Delta y_2 - \Delta y_1, \quad \dots, \quad \Delta^2 y_{n-2} = \Delta y_n - \Delta y_{n-1} \quad (4.2)$$

Here, $\Delta^2 y_0 = \Delta y_1 - \Delta y_0 = y_2 - y_1 - (y_1 - y_0) = y_2 - 2y_1 + y_0$.

Higer Order Forward Differences

Here, $\Delta^3 y_0 = \Delta^2 y_1 - \Delta^2 y_0 = \Delta y_2 - \Delta y_1 - (\Delta y_1 - \Delta y_0) = \dots = y_3 - 3y_2 + 3y_1 - y_0$.

The coefficients occuring are the **binomial coefficients**.

Programming

For practical computations, the following notation is useful: $y_j = DEL(0, j)$, and

$$\begin{aligned} \Delta y_j &= DEL(0, j+1) - DEL(0, j) \\ \Delta^i y_j &= DEL(i-1, j+1) - DEL(i, j) \end{aligned}$$

4.2.2 Backward Differences

The backward difference ∇y_{i+1} is defined as $\nabla y_{i+1} = y_{i+1} - y_i$, where ∇ is called the *backward difference operator*. We have,

$$\nabla y_1 = y_1 - y_0, \quad \nabla y_2 = y_2 - y_1, \quad \dots, \quad \nabla y_n = y_n - y_{n-1} \quad (4.3)$$

These differences ∇y_{i+1} , $i = 0, 1, \dots, (n - 1)$ are called *first backward differences*.

- For $(n + 1)$ points, there are n backward differences.
- These n -backward differences begin at ∇y_1 , and end at ∇y_n . There is no ∇y_0 .

Second Backward Differences

The backward differences of the first backward differences are called second backward differences. They are denoted by $\nabla^2 y_{i+2}$, $i = 0, 1, \dots, (n - 2)$. That is,

$$\nabla^2 y_2 = \nabla y_2 - \nabla y_1, \quad \nabla^2 y_3 = \nabla y_3 - \nabla y_2, \quad \dots, \quad \nabla^2 y_n = \nabla y_n - \nabla y_{n-1} \quad (4.4)$$

Here, $\nabla^2 y_2 = \nabla y_2 - \nabla y_1 = y_2 - y_1 - (y_1 - y_0) = y_2 - 2y_1 + y_0$.

Higer Order Backward Differences

Here, $\nabla^3 y_3 = \nabla^2 y_3 - \nabla^2 y_2 = \nabla y_3 - \nabla y_2 - (\nabla y_2 - \nabla y_1) = \dots = y_3 - 3y_2 + 3y_1 - y_0$.

The coefficients occuring are the **binomial coefficients**.

4.2.3 Central Differences

The central difference $\delta y_{i+1/2}$ is defined as $\delta y_{i+1/2} = y_{i+1} - y_i$, where δ is called the *central difference operator*. We have,

$$\delta y_{1/2} = y_1 - y_0, \quad \delta y_{3/2} = y_2 - y_1, \quad \dots, \quad \delta y_{(2n-1)/2} = y_n - y_{n-1} \quad (4.5)$$

These differences $\delta y_{i+1/2}$, $i = 0, 1, \dots, (n-1)$ are called *first central differences*.

- For $(n+1)$ points, there are n first central differences.
- These n -central first differences begin at $\delta y_{1/2}$, and end at $\delta y_{(2n-1)/2}$.

Second Central Differences

The central differences of the first central differences are called second central differences. They are denoted by $\delta^2 y_i$, $i = 1, \dots, (n-1)$ $\delta^2 y_i = \delta y_{i+1/2} - \delta y_{(i-1)+1/2}$. That is,

$$\delta^2 y_1 = \delta y_{3/2} - \delta y_{1/2}, \quad \delta^2 y_2 = \delta y_{5/2} - \delta y_{3/2}, \quad \dots, \quad \delta^2 y_{n-1} = \delta y_{(2n-1)/2} - \delta y_{(2n-3)/2} \quad (4.6)$$

Here, $\delta^2 y_1 = \delta y_{3/2} - \delta y_{1/2} = y_2 - y_1 - (y_1 - y_0) = y_2 - 2y_1 + y_0$.

Higer Order Central Differences

Here, $\delta^3 y_{3/2} = \delta^2 y_2 - \delta^2 y_1 = \delta y_{5/2} - \delta y_{3/2} - (\delta y_{3/2} - \delta y_{1/2}) = \dots = y_3 - 3y_2 + 3y_1 - y_0$.

4.2.4 Equivallency of the differences

From the above subsections we can see that, the same numbers occurs at the same positions whether we use forward backward or central differences. That is,

$$\Delta y_0 = \nabla y_1 = \delta y_{1/2}, \quad \Delta^2 y_0 = \nabla^2 y_1 = \delta^2 y_1, \quad \Delta^3 y_0 = \nabla^3 y_3 = \delta^3 y_{3/2}$$

4.3 Newton's formula for Interpolation

Given $(n+1)$ points, $(x_0, y_0), (x_1, y_1), \dots, (x_n, y_n)$ of x and $y(x)$, with x values equally spaced, we find a polynomial $y_n(x)$ of n th degree such that, $y(x)$ and $y_n(x)$ agree at the given points. If we consider $y_n(x)$ to be the polynomial:

$$y_n(x) = a_0 + a_1(x - x_0) + a_2(x - x_0)(x - x_1) + a_3(x - x_0)(x - x_1)(x - x_2) + \dots + a_n(x - x_0)(x - x_1)\dots(x - x_{n-1}). \quad (4.7)$$

$$\text{Then, } a_0 = y_0, \quad a_1 = \frac{y - y_1}{x_1 - x_0} = \frac{\Delta y_0}{h}, \quad a_2 = \frac{\Delta^2 y_0}{2! h^2}, \quad a_3 = \frac{\Delta^3 y_0}{3! h^3}, \quad \dots, \quad a_n = \frac{\Delta^n y_0}{n! h^n}$$

where, h is the $x_i - x_j$, $i \neq j$.

Setting $x = x_0 + ph$, we get,

$$y_n(x) = y_0 + p\Delta y_0 + \frac{p(p-1)}{2!} \Delta^2 y_0 + \frac{p(p-1)(p-2)}{3!} \Delta^3 y_0 + \dots + \frac{p(p-1)(p-2)\dots(p-(n-1))}{n!} \Delta^n y_0 \quad (4.8)$$

This formula 4.8 is the **Newton's forward difference interpolation** formula.

4.3.1 Newton's backward difference Interpolation

If we consider $y_n(x)$ to be the polynomial:

$$y_n(x) = a_0 + a_1(x - x_n) + a_2(x - x_n)(x - x_{n-1}) + a_3(x - x_n)(x - x_{n-1})(x - x_{n-2}) + \dots + a_n(x - x_n)(x - x_{n-1})(x - x_{n-2})\dots(x - x_1). \quad (4.9)$$

Then we get the following formula for $y_n(x)$.

$$y_n(x) = y_n + p\nabla y_n + \frac{p(p-1)}{2!} \nabla^2 y_n + \frac{p(p-1)(p-2)}{3!} \nabla^3 y_n + \dots + \frac{p(p-1)(p-2)\dots(p-(n-1))}{n!} \nabla^n y_n \quad (4.10)$$

This formula 4.10 is the **Newton's backward difference interpolation** formula.

Remark. The Newton's forward difference interpolation formula is useful for interpolating near the beginning of the tabular values and the Newton's backward difference interpolation formula is useful for interpolating near the end of the tabular values.

Estimate the values of $f(x)$ at $x = 0.98, 1.02, 1.12, 1.16, 1.27, 1.34$ from the given data values: $(1.00, 2.7183)$, $(1.05, 2.8577)$, $(1.10, 3.0042)$, $(1.15, 3.1582)$, $(1.20, 3.3201)$, $(1.25, 3.4903)$, $(1.30, 3.6693)$.

Given: $h = 0.05, x_0 = 1.00, x = 0.98$

$$\Rightarrow p = \frac{0.98-1.00}{0.05} = -0.4$$

Newton's forward formula: $y_n(x) =$

$$y_0 + p \frac{\Delta y_0}{1!} + p(p-1) \frac{\Delta^2 y_0}{2!} + p(p-1)(p-2) \frac{\Delta^3 y_0}{3!} + \dots$$

$$= 2.7183 + (-0.4)(0.1394) + \frac{(-0.4)(-1.4)}{2} (0.0071) + \frac{(-0.4)(-1.4)(-2.4)}{6} (0.0004)$$

$$= 2.6644$$

Now, for $x = 1.02, p = \frac{1.02-1}{0.05} = 0.4$.

Then, $y_n = 2.77$.

For $x = 1.27$, we have, $h = 0.05, x_n = 1.30 \Rightarrow p = \frac{1.27-1.30}{0.05} = -0.6$

Newton's backward formula:

$$y_n(x) = y_n + p \frac{\nabla y_n}{1!} + p(p+1) \frac{\nabla^2 y_n}{2!} + p(p+1)(p+2) \frac{\nabla^3 y_n}{3!} + \dots$$

$$= 3.6693 + (-0.6)(0.1790) + \frac{(-0.6)(0.4)}{2} (0.0088) + \frac{(-0.6)(0.4)(1.4)}{6} (0.0005)$$

$$= 3.561$$

Now, for $x = 1.34, p = \frac{1.34-1}{0.05} = 0.8$. Then, $y_n = 3.6726$.

1. Find the cubic polynomial which takes the following values: $y(1) = 24$, $y(3) = 120$, $y(5) = 336$, $y(7) = 720$. Then obtain the value of $y(8)$.
2. Find a cubic polynomial which fits the data: $(-2, -12)$, $(-1, -8)$, $(2, 3)$, $(3, 5)$.

4.4 Interpolation with Unevenly spaced points

This section discusses the interpolation method for unequally spaced values of the argument.

4.4.1 Lagrange's Interpolation Formula

Let $y(x)$ be continuous and differentiable $(n + 1)$ times in the interval (a, b) . Given $(n + 1)$ points, $(x_0, y_0), (x_1, y_1), \dots, (x_n, y_n)$ of x and $y(x)$, where x values not necessarily equally spaced, we find a polynomial $L_n(x)$ of n th degree such that, $y(x)$ and $L_n(x)$ agree at the given points.

The formula $\sum_{i=0}^n l_i(x) y_i$, where $l_i(x) = \frac{(x - x_0)(x - x_1)\dots(x - x_{i-1})(x - x_{i+1})\dots(x - x_n)}{(x_i - x_0)(x_i - x_1)\dots(x_i - x_{i-1})(x_i - x_{i+1})\dots(x_i - x_n)}$ is called the Lagrange's Interpolating formula.

Example

Estimate the value of $f(301)$ from the following data values:

$(300, 2.4771), (304, 2.4829), (305, 2.4843), (307, 2.4871)$.

Since, we have 4 data points, Using Lagrange's third degree polynomial,

$$\begin{aligned} L_3(x) &= \frac{(x-x_1)(x-x_2)(x-x_3)}{(x_0-x_1)(x_0-x_2)(x_0-x_3)}y_0 + \frac{(x-x_0)(x-x_2)(x-x_3)}{(x_1-x_0)(x_1-x_2)(x_1-x_3)}y_1 \\ &\quad + \frac{(x-x_0)(x-x_1)(x-x_3)}{(x_2-x_0)(x_2-x_1)(x_2-x_3)}y_2 + \frac{(x-x_0)(x-x_1)(x-x_2)}{(x_3-x_0)(x_3-x_1)(x_3-x_2)}y_3 \\ L_3(301) &= \frac{(-3)(-4)(-6)}{(-4)(-5)(-7)}2.4771 + \frac{(1)(-4)(-6)}{(4)(-1)(-3)}2.4829 \\ &\quad + \frac{(1)(-3)(-6)}{(5)(1)(-2)}2.4843 + \frac{(1)(-3)(-4)}{(7)(3)(2)}2.4871 \\ &= 1.2739 + 4.9658 - 4.4717 + 0.7106 \\ &= 2.4786 \end{aligned}$$

Exercise

1. Estimate the value of $f(0.7)$ from the following data values:

$(0, 1), (0.4, 1.8556), (0.9, 2.5868), (1.2, 2.1786), (1.5, 0.4167)$

2. Find $f(x)$ as a polynomial in x from the following data:

$(0, -12), (1, 0), (3, 12), (4, 24)$

4.4.2 Disadvantage of Lagrange's Interpolation

The Lagrange's Interpolation formula has the disadvantage that if another interpolation point were added, then interpolation coefficients $l_i(x)$ will have to be recomputed. We therefore see an interpolation polynomial which has the property that a polynomial of higher degree may be derived from it by simply adding new terms. Newton's general interpolation formula is one such formula.

4.5 Divided Differences

Given $(n+1)$ points, $(x_0, y_0), (x_1, y_1), \dots, (x_n, y_n)$ of x and $y(x)$, with x values equally spaced, the divided differences of order 1, 2, ..., n are defined by the relations:

$$\begin{aligned} [x_0, x_1] &= \frac{y_1 - y_0}{x_1 - x_0} \\ [x_0, x_1, x_2] &= \frac{[x_1, x_2] - [x_0, x_1]}{x_2 - x_0} \\ &\dots \\ [x_0, x_1, x_2, \dots, x_n] &= \frac{[x_1, x_2, \dots, x_n] - [x_0, x_1, \dots, x_{n-1}]}{x_n - x_0} \end{aligned}$$

It is easy to see that, $[x_0, x_1] = \frac{y_1 - y_0}{x_1 - x_0} = \frac{y_0}{x_0 - x_1} + \frac{y_1}{x_1 - x_0} = [x_1, x_0]$. Again,

$$\begin{aligned} [x_0, x_1, x_2] &= \frac{[x_2, x_0] - [x_0, x_1]}{x_2 - x_0} \\ &= \frac{1}{x_2 - x_0} \left[\frac{y_2 - y_1}{x_2 - x_1} - \frac{y_1 - y_0}{x_1 - x_0} \right] \\ &= \frac{1}{x_2 - x_0} \left[\frac{y_2}{x_2 - x_1} - y_1 \left(\frac{1}{x_2 - x_1} + \frac{1}{x_1 - x_0} \right) + \frac{y_0}{x_1 - x_0} \right] \\ &= \frac{y_0}{(x_0 - x_1)(x_0 - x_2)} + \frac{y_1}{(x_1 - x_0)(x_1 - x_2)} + \frac{y_2}{(x_2 - x_0)(x_2 - x_1)} \end{aligned}$$

$$\begin{array}{lcl} x_0 & y_0 & \\ & [x_0, x_1] = \frac{y_1 - y_0}{x_1 - x_0} & \\ x_1 & y_1 & \\ & [x_0, x_1, x_2] = \frac{[x_1, x_2] - [x_0, x_1]}{x_2 - x_0} & \\ & [x_1, x_2] = \frac{y_2 - y_1}{x_2 - x_1} & [x_0, x_1, x_2, x_3] = \frac{[x_1, x_2, x_3] - [x_0, x_1, x_2]}{x_3 - x_0} \\ x_2 & y_2 & \\ & [x_1, x_2, x_3] = \frac{[x_2, x_3] - [x_1, x_2]}{x_3 - x_1} & \\ & [x_2, x_3] = \frac{y_3 - y_2}{x_3 - x_2} & \\ x_3 & y_3 & \end{array}$$

4.5.1 Newton's General Interpolation Formula

We have, $[x, x_0] = \frac{y - y_0}{x - x_0} \implies y = y_0 + (x - x_0)[x, x_0]$

And $[x, x_0, x_1] = \frac{[x, x_0] - [x_0, x_1]}{x - x_1} \implies [x, x_0] = [x_0, x_1] + (x - x_1)[x, x_0, x_1]$

From these two relations we get,

$$y = y_0 + (x - x_0)[x_0, x_1] + (x - x_0)(x - x_1)[x, x_0, x_1] \quad (4.11)$$

Similarly we can get $[x, x_0, x_1] = [x_0, x_1, x_2] + (x - x_2)[x, x_0, x_1, x_2]$ and so on... Proceeding this way we get,

$$\begin{aligned} y = y_0 &+ (x - x_0)[x_0, x_1] + (x - x_0)(x - x_1)[x_0, x_1, x_2] + \\ &(x - x_0)(x - x_1)(x - x_2)[x_0, x_1, x_2, x_3] + \dots \\ &+ (x - x_0)(x - x_1)(x - x_2)\dots(x - x_n)[x, x_0, x_1, \dots, x_n] \end{aligned} \quad (4.12)$$

This Equation 4.12 is called the Newton's general interpolation formula with divided differences.

Example

Estimate the value of $f(301)$ from the following data values:
 $(300, 2.4771), (304, 2.4829), (305, 2.4843), (307, 2.4871)$.

The divided difference table is

300	2.4771		
		0.00145	
304	2.4829		-0.00001
		0.00140	
305	2.4843		0
		0.00140	
307	2.4871		

From Newton's divided difference formula, we have

$$y = y_0 + (x - x_0)[x_0, x_1] + (x - x_0)(x - x_1)[x_0, x_1, x_2] + (x - x_0)(x - x_1)(x - x_2)[x_0, x_1, x_2, x_3] + \dots$$

$$f(301) = 2.4771 + (301 - 300)(0.00145) + (301 - 300)(301 - 304)(-0.00001)$$

$$f(301) = 2.4786$$

Exercise

1. Estimate the value of $f(0.7)$ from the following data values:

$(0, 1), (0.4, 1.8556), (0.9, 2.5868), (1.2, 2.1786), (1.5, 0.4167)$

2. Find $f(x)$ as a polynomial in x from the following data:

$(-1, 3), (0, -6), (3, 39), (6, 822), (7, 1611)$

4.6 Inverse Interpolation

Given a set of values of x and y , the process of finding the value of x for a certain value of y is called inverse interpolation.

- When the values of x are at unequal intervals, the most obvious way of performing this process is by interchanging x and y in Lagrange's method.
- When the values of x are equally spaced, the method of successive approximations on Newton's method should be used.
